

# Beam SDKs Don't Have to Look the Same

A Quick Look at an alternative Go SDK design

Robert Burke  
lostluck@apache.org

BEAM  
SUMMIT

September 4-5, 2024  
Sunnyvale, CA. USA

We know what a Beam SDK looks like, right?

BEAM  
SUMMIT

```
@OnTimer (END_OF_BUFFERING_ID)
```

```
PCollection<Integer> wordLengths = words.apply( receiver,  
    MapElements.into(TypeDescriptors.integers())  
    .via((String word) -> word.length()));
```

```
class FooFn extends DoFn<S  
@ProcessElement
```

```
public void processElement( WindowExpiration
```

```
@FinalOutput  
public void writeBundle (F
```

```
@StateId (NUM_ELEMENTS_IN_ On_ C_ ingState<Long,  
long[], Long> storedBat_ Siz_ /  
@Timer (END_OF_BUFFERING_ Timer_ k_ fer_ Timer,  
name = TIMER_HO_ T_ l_ timer) { ... }
```

```
onWindowExpiration (
```

```
OutputReceiver<KV<K, Iterable<InputT>>> receiver,  
@Key K key,
```

```
[Final Output PCollection] = [Initial Input PCollection].apply([First Transform] ate<Long,  
    .apply([Second Transform])  
    .apply([Third Transform])
```

BEAM SDK

```
@on_timer(WATERMARK_TIMER)
```

```
word_lengths = words | beam.FlatMap(lambda word: [len(word)])
```

```
def start_bundle(self):
```

```
    window=beam.DoFn.WindowParam,  
    key=beam.DoFn.KeyParam,  
    buffer_1=beam.DoFn.StateParam(BUFFER_STATE_1),
```

```
class FooFn(beam.DoFn):
```

```
    def process(self, element, restriction):
```

```
        buffer_2=beam.DoFn.StateParam(BUFFER_STATE_2):
```

```
            def create_watermark_estimator(self, element, restriction):
```

```
def start_bundle(self):
```

```
    def create_watermark_estimator(self, state):
```

```
[Final Output PCollection] = ([Initial Input PCollection] | [First Transform]  
    | [Second Transform]  
    | [Third Transform])
```

```
func (fn *FooFn) OnTimer(sp state.Provider,
```

```
func wordLengths(word string) int { return len(word) }  
func init() { register.Function1x1(wordLengths) }
```

```
func applyWordLenAnon(s beam.Scope, words beam.PCollection) beam.PCollection {  
    return beam.ParDo(s, wordLengths, words)  
}
```

```
type BeamRestrictor struct {  
    func init() { register.DoFnRestrictor("beam", "BeamRestrictor", &BeamRestrictor{})
```

```
func (r *BeamRestrictor) Process(f func() SplitRestriction) SplitRestriction(filename string, rest  
func (r *BeamRestrictor) Restrict(f func() BeamRestrictor) BeamRestrictor(filename string, rest  
func (r *BeamRestrictor) Restrict(f func() BeamRestrictor) BeamRestrictor(filename string, rest
```

```
[Second PCollection] := beam.ParDo(scope, [First Transform], [Initial Input  
PCollection])  
[Third PCollection] := beam.ParDo(scope, [Second Transform], [Second  
PCollection])  
[Final Output PCollection] := beam.ParDo(scope, [Third Transform], [Third  
PCollection])
```

One of these things are not like the others

BEAM  
SUMMIT

# The Differences with Go

vs Java and Python

- No Overloading
  - Prevents `PCollection.apply` like syntax
- No Inheritance
  - DoFns and their methods are inferred reflectively\*
- No built in Serialization or Pickling
  - Prevents closures and reliable anonymous functions
- No Annotations
  - Prevents targeting methods or fields for specific uses.
- No Generics
  - SDK must typecheck itself.
- No user defined Iterators

**BEAM**

# The Differences with Go

vs Java and Python

- No Overloading
  - Prevents PCollection.apply like syntax
- No Inheritance
  - DoFns and their methods are inferred reflectively\*
- No built in Serialization or Pickling
  - Prevents closures and reliable anonymous functions
- No Annotations
- ~~● No Generics~~
  - SDK must typecheck itself?
- ~~● No user defined Iterators~~

BEAM  
SUMMIT

# Why these aspects matter

- Affects how discoverable features are to users
  - IDE Support, Documentation
- Affects how we can add features to the SDK
  - How much code is required to correctly implement a feature
- Affects performance at construction time
  - Is the framework aware of this features use?
  - Can the SDK put it into the portable pipeline graph?
  - Can the compiler prevent mistakes entirely?
- Affects performance at execution time
  - Can the SDK make better choices for efficient execution?

The Challenge:

Does a Beam SDK *\*have\** to look like that?

BEAM  
SUMMIT

# An alternative Go SDK

Designed for Today's Go

- Make use of Generics
- Not constrained to look like existing SDKs
- Not constrained by compatibility.
- Can it be easier for users?
- Can it be easier for maintainers?

BEAM  
SUMMIT

# What can we do differently, with Today's Go?

- How small can we make the User API surface?
- Can we have compile time type safety at pipeline construction?
- Can we reduce the burden of graph construction?
- Can we avoid Registering DoFns?
- Can we enable anonymous funcs or closures?
- <many more questions>

BEAM  
SUMMIT

# Reading Go - quick notes

- Types are specified after names,
  - “var name string”
- Function return types are after the parameters
  - `func calculateWeight(thing MyThing) float64 { ... }`
- Generic Type Parameters are declared in square brackets
  - `type MyCollection[T any] struct{ ... }`

```

type MyDoFn struct{
  Config string
  Side SideInputMap[int, string]
  Exceptions beam.CounterInt64
  Out beam.Output[string]
  beam.OnFinishBundle
}

func (fn *MyDoFn) ProcessBundle(dfc *beam.DFC[string]) error {
  ...
}

```

Serializable configuration  
 Static types for Side input  
 Access pattern  
 Metrics!  
 Statically typed output emitters!  
 Types for specialized features  
 Single method to implement

```

type MyDoFn struct{ ... }

func (fn *MyDoFn) ProcessBundle(dfc *beam.DFC[string]) error {
    // StartBundle happens on the ProcessBundle call

    // Configure the ProcessElement function on the DFC.
    dfc.Process(func(ec beam.ElmC, elm string) error {
        fn.Processed.Inc(dfc, 1)
        fn.Output.Emit(ec, newElm)
        return nil
    })

    fn.OnBundleFinish.Do(dfc, func() error {
        // Do some FinishBundle in the callback.
        return nil
    })
    // Per Bundle state cleaned up by Garbage collector
    return nil
}

```

# Field Based Design

- Allows users to express intent around
  - DoFn configuration
  - Access Metadata
  - Side Metrics
  - Counters
  - State
  - Timers
  - Emitters
- Framework can observe that intent ahead of time

```
type MyDoFn struct{
    Config string

    Side SideInputMap[int, string]

    Exceptions beam.CounterInt64
    Size       beam.DistributionInt64

    LastVal beam.StateValue[string]
    Callback beam.TimerEventTime

    Out beam.Output[string]
    Partition []beam.Output[string]

    beam.OnFinishBundle
    beam.ObserveWindow
}
```

# Combiners

- Dedicated “shape” based wrapper functions to build.
  - beam.FullCombine
  - beam.SimpleMerge
  - beam.AddMerge
  - beam.MergeExtract
- To be used by both
  - beam.CombinePerKey(
  - beam.CombineGlobal

```
type MeanFn[E constraints.Integer | constraints.Float] struct{}
```

```
type meanAccum[E constraints.Integer | constraints.Float] struct {  
    Count int32  
    Sum E  
}
```

```
func (MeanFn[E]) AddInput(a meanAccum[E], i E) meanAccum[E] {  
    a.Count += 1  
    a.Sum += i  
    return a  
}
```

```
func (MeanFn[E]) MergeAccumulators(a meanAccum[E], b meanAccum[E])  
meanAccum[E] {  
    return meanAccum[E]{Count: a.Count + b.Count, Sum: a.Sum + b.Sum}  
}
```

```
func (MeanFn[E]) ExtractOutput(a meanAccum[E]) float64 {  
    return float64(a.Sum) / float64(a.Count)  
}
```

```
...  
beam CombinePerKey(s, keyedSrc.Output,  
    beam FullCombine(MeanFn[int]{}))  
...
```

**BEAM**  
SUMMIT

# Compile Time type safety

- Need to have element types in the processing method type.
- Need to have a way of indicating output types.
- Want to have pipeline safety at compile time

# Pipeline Construction

- Happens in a function provided to beam.Run
  - A “no pipeline approach”
  - Allows inline, or separated construction
- Also serves as the “init” switch
- Still to come: Operational Options
  - Construction time options
  - Worker side options

```
pr, err := beam.Run(ctx, func(s *beam.Scope) error {
    imp := beam.Impulse(s)
    src := beam.ParDo(s, imp, &SourceFn{
        Count: 10,
    })
    other := beam.ParDo(s, imp, &OtherSourceFn{
        Config: "configuration!",
    })
    inc := beam.ParDo(s, src.Output, &MyIncDoFn{
        Side: beam.AsSidelter(other.Output)
    })
    lw := beam.Map(s, inc.Output, func(v int) int { return v - 1 },
beam.Name("Decrement"))
    beam.ParDo(s, lw, &DiscardFn[int]{}), beam.Name("sink"))
    return nil
}, beam.Name("testjob"))
```

# How do workers work?

- Pipeline Construction is re-done to register DoFns on the worker.
  - Non-deterministic construction could cause problems. Mitigatable by computing non-deterministic values at construction time, and transmitting them via pipeline options.
- Bundle Processing DoFns are strung together in a type safe way via reflection, and the DFC parameter.
  - Details are not included in this talk.
- Very little between DoFns: Outputs nearly directly passed to consumers

# What about Splittable DoFns?

Still in progress, current attempt:

```
type BoundedSDF[FAC RestrictionFactory[E, R, P], E any, T Tracker[R, P], R  
Restriction[P], P, WES any] struct{
```

```
fn.BoundedSDF.Process(dfc,  
    func(rest OffsetRange) *ORTracker {...},  
    func(ec ElmC, elm int, or OffsetRange, tc TryClaim[int64]) error { ... })
```

# Future Work

- Submit jobs to Dataflow
  - Can already execute in Docker!
- State and Timer support
- Windowing Strategy and Triggers

# What can we do differently, with Today's Go?

- How small can we make the User API surface?
  - YES!
- Can we have compile time type safety at pipeline construction?
  - YES!
- Can we reduce the burden of graph construction?
  - A little.
- Can we avoid Registering DoFns?
  - Yes!
- Can we enable anonymous funcs or closures?
  - Yes!

```
lw := beam.Map(inc.Output, func(v int) int { return v + 1 })
```

Start bundle in ProcessBundle

```
type FooFn struct {  
    Output beam.Output[string]  
}
```

Finalize bundle in ProcessBundle

```
fn1 := beam.ParDo(scope [Initial Input collection], dof1)  
fn2 := beam.ParDo(scope [fn1 Output], dof2)  
dof := beam.ParDo(scope [fn2 Output], dof3)
```

```
type MyDoFn struct {
```

```
    StateInputMap [int, string]
```

```
    Example beam.Output[Int64]
```

```
    StateOutput beam.Output[Int64]
```

```
    CallBack beam.TimerEventTime
```

```
    Out beam.Output[string]
```

```
    Partition []beam.Output[string]
```

THAN YOU!

BEAM?!
